FAB3102
2.0 Watt Class-D Audio Amplifier with Integrated Boost Regulator and Automatic Gain Control

Features

- High Output, High-Efficiency, Class-D Mono Speaker Amplifier

- Low EMI Design Allows Filterless Operation

- High Noise Rejection Using Differential Audio Inputs

- High-Efficiency Boost Regulator Provides Higher Output Power Over Battery Voltages

- Boost Shutdown at Lower Output Power Increases Efficiency and Reduces Quiescent Current Consumption

- Automatic Gain Control (AGC) Monitors Battery Voltage and Dynamically Adjusts Gain, Extending Battery Runtime

- Short-Circuit Protection

- Low-Voltage Shutdown

- Click and Pop Suppression

- Available in 12-Bump WLCSP

Description

The FAB3102 is a mono, Class-D, boosted audio amplifier with differential audio inputs.

An integrated boost regulator allows for high output power over a power supply range of 2.5V to 5.2V. At low output power, the boost regulator automatically shuts down for greater efficiency and lower quiescent current consumption.

Automatic Gain Control (AGC) reduces gain when the power supply voltage is low to limit maximum current consumption.

Pin Definitions

WLCSP	Name	Type	Description
B1	OUT+	Output	Positive audio output
C1	OUT-	Output	Negative audio output
C3	IN+	Analog input	Positive audio input
D3	IN-	Analog input	Negative audio input
C2	EN	CMOS input	Shutdown signal for boost regulator and amplifier: VBATT=enabled, PGND=shutdown (internal 300KΩ pull-down)
B2	AGCT	Analog input	AGC trip point setting
B3	VBATT	Power	Supply voltage
A2	SW	Power	Boost regulator switching node
A1	PVDD	Power	Boost regulator output
A3	BGND	Ground	Boost regulator ground – connect to PGND and AGND with a ground plane.
D1	PGND	Ground	Power ground – connect to BGND and AGND with a ground plane.
D2	AGND	Ground	Analog ground – connect to BGND and PGND with a ground plane.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.

Symbol	Parameter	Min.	Max.	Unit
V_{BATT}	Voltage on VBATT Pin	-0.3	6.0	V
V_{OUT}	Voltage on OUT-, OUT+ Pin	-0.3	V_{BSTOUT} + 0.3	V
V_{IN}	Voltage on SW, IN-, IN+, EN, AGCT Pin	-0.3	V_{BATT} + 0.3	V

Detailed Description

Signal Path

The FAB3102 features a fully differential signal path for noise rejection. The low-EMI design allows the OUT+ and OUT- pins to be connected directly to a speaker without an output filter.

The input section includes an 80KHz low-pass filter for removing out-of-band noise from audio sources, such as sigma delta DACs.

Shutdown

If EN is grounded, the Class-D amplifier and the boost regulator are turned off. IN+ and IN- are high impedance. Audio signals present at IN+ and IN- with amplitude less than the maximum differential input voltage swing are not distorted by the FAB3102 (*see electrical characteristics*).

When EN transitions from LOW to HIGH, during the wake-up time *(see Electrical Characteristics)* the FAB3102 charges the input DC blocking capacitors to the Common Mode voltage before enabling the Class-D amplifier. To minimize click and pop during turn-on, audio signals should not be present during the wake-up period. Other devices that are connected to the same input signal, if not muted, may experience a pop due to this capacitor charging.

There is no limitation on the length of shutdown. Remaining charge on the PVDD capacitor at startup (for example, if EN is LOW for only a short period) does not affect startup behavior.

The EN pin has an internal 300KΩ pull-down resistor.

EN must be LOW when V_{BATT} is lower than the V_{BATT} under-voltage shutdown voltage *(see Electrical Characteristics)*. EN must remain LOW for at least 100µs after V_{BATT} rises above the V_{BATT} under-voltage shutdown voltage.

Class-D Amplifier Over-Current Protection

If the output current of the Class-D amplifier exceeds limits *(see the Electrical Characteristics)*, the amplifier is disabled for approximately one second. (Other systems, such as the boost regulator and AGC, remain active.) After one second, the amplifier is re-enabled. If the fault condition still exists, the amplifier is disabled again. This cycle repeats until the fault condition is removed.

Low EMI

To minimize EMI, edge rate control for the boost regulator and Class-D amplifier can be employed.

The boost regulator's rise and fall times are set to 20ns per transition by default. For devices with 10ns boost edge rates or disabled boost regulator edge-rate control, contact a Fairchild Representative. This is a factory option that cannot be changed in the application.

The Class-D amplifier's edge rate control is disabled by default. For devices with 20ns Class-D edge rates, contact a Fairchild Representative. This is a factory option that cannot be changed in the application.

Automatic Boost Shutdown

Automatic boost shutdown changes the Class-D amplifier supply voltage as a function of audio output level. At audio output levels above $2V_{pk}$, the boost converter generates 5.65V from the input battery voltage. If the output level is below $2V_{pk}$ for more than 125ms, the boost converter is switched off and the Class-D amplifier is supplied directly from the battery. As a result, efficiency is improved at low audio output levels and quiescent current consumption is reduced.
Figure 19. Auto Boost Startup

Figure 19 shows an example of an auto boost startup event. At first, the boost converter is off and PVDD is the same voltage as VBATT. At 20µs, a large audio signal is presented at the inputs, which causes the boost converter to start up. From 20µs to 120µs, battery current is ramped up from 0A to the auto boost startup current Limit of 1.5A for the duration of the auto boost startup time. The auto boost startup current ramp rate is 15mA/µs. These limits are enforced to avoid sudden current draw spikes from the battery.

At 120µs, after the auto boost startup time, the ramp is released and battery current falls to a level capable of sustaining the speaker amplifier's outputs. At 160µs, the input signal begins to rise, which increases battery current. At 180µs, the boost converter peak input current limit is enforced and battery current levels off, which causes PVDD to droop.

The boost regulator should not be used to drive any loads other than the Class-D amplifier.

Automatic Gain Control

Due to constant output power, the amount of VBATT current needed to maintain a given output amplitude is inversely proportional to VBATT voltage. This produces very large current requirements at low V_{BATT}. The AGC eases low-VBATT current demands by reducing the gain when VBATT voltage drops below a trip point. One of three different trip points may be selected by shorting AGCT to VBATT, shorting AGCT to PGND, or floating *AGCT (see Electrical Characteristics)*.

The trip point is determined upon power-on and when EN transitions from LOW to HIGH. If AGCT is changed during operation, the new value is not read until power or EN is cycled.

When V_{BATT} is above the trip point, the AGC has no effect on the signal path.

When V_{BATT} is at or below the trip point, target gain is reduced in 0.5dB steps according to the equation:

$$G_{t\arg et} = G_I - S_L G_I \left(\frac{V_T - V_{batt}}{V_{out\max}} \right) \qquad (1)$$
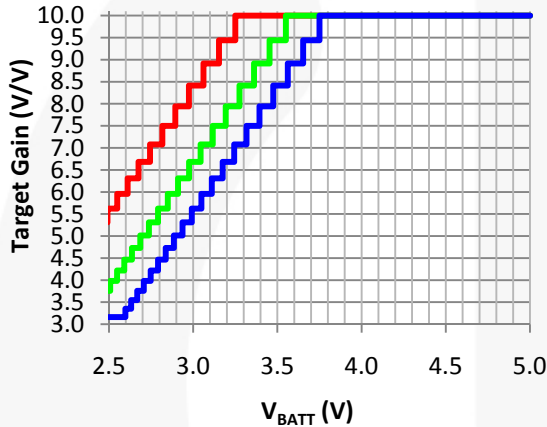

where:

G_I	= Initial Gain (10V/V);
S_L	= 3V/V Slope;
V_{OUTMAX}	= 5.2V;
V_T	= AGC Trip Point Set by the AGCT Pin; and
V_{BATT}	= Voltage at the VBATT Pin.

Target gain can be reduced by as much as 10dB.

Note that the state of auto boost shutdown has no effect on the AGC.

Figure 20 shows target gain vs. battery voltage.

Cyan	Ground	3.55	0.3
Black	V_{BATT}	3.75	0.3

Figure 23. Output Power vs. Battery Voltage Examples (V_{IN}=0.4V_{pk} Sine)

The speed at which gain can change is limited *(see Electrical Characteristics)*; therefore, the actual gain may lag the target gain if V_{BATT} voltage changes quickly.

Figure 24 and Figure 25 show examples of AGC changes over time. In these examples, AGCT is grounded, so the AGC trip point is 3.55V.

1. Initially, V_{BATT} is 3.6V and gain is 10V/V (20dB).

2. A narrow V_{BATT} drop of less than 2µs is ignored by the AGC.

3. The next V_{BATT} drop lasts longer and the AGC is tripped. The initial 0.5dB gain reduction occurs 3.9µs after V_{BATT} crosses below the 3.55V trip point.

4. V_{BATT} is now 3.1V, so target gain is 10V/V – 3V/V × 10V/V × [(3.55V – 3.1V) / 5.2V]=7.40V/V=17.4dB.

5. Gain continues to drop by 0.5dB every 10µs until it is below the target gain, where it settles at 17.0dB.

6. When V_{BATT} rises above the trip point, gain increases by 0.5dB. If more than 800ms has passed since the last gain change, gain rises immediately as shown in Figure 24. Otherwise, gain does not rise until after 800ms has passed, as shown in Figure 25.

7. While V_{BATT} remains above the trip point, gain continues to increase by 0.5dB every 800ms until it returns to 20dB.

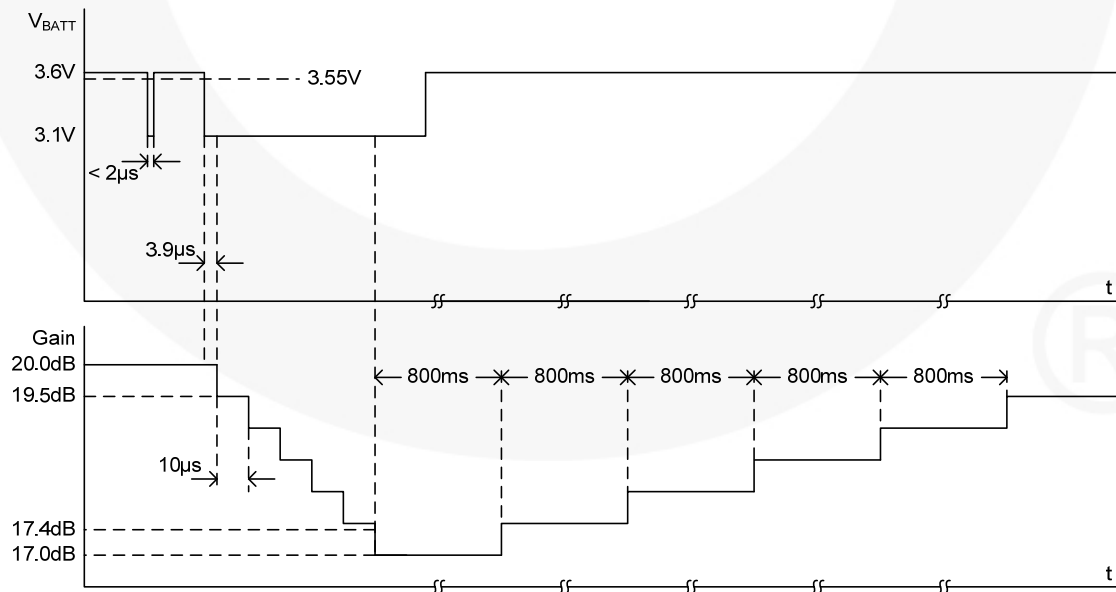

Figure 24. AGC Changes vs. Time, Example 1

Figure 25. AGC Changes vs. Time, Example 2

The intent of the AGC circuitry is to limit current draw from the battery to extend runtime. This is particularly important for handsets that incorporate advanced shutdown algorithms that measure battery voltage. The AGC circuit dynamically adjusts the amplifier gain depending on the trip point used. Even though the amplifier gain is reduced in response to lower battery voltages, two conditions result in continued higher current draw: 1) the handset volume is turned up in an attempt to maintain the same loudness, or 2) the input signal is increased. If one or both of these conditions exist, even though the amplifier gain is reduced in response to lower battery voltage, current draw remains elevated, eventually resulting in handset shutdown.

Applications Information

Layout Considerations

General layout and supply bypassing play a major role in analog performance and thermal characteristics. Fairchild offers an evaluation board to guide layout and aid device evaluation. Following this layout configuration provides optimum performance for the device. For best results, follow the steps and recommended routing rules listed below.

Recommended Routing/Layout Rules

- Do not run analog and digital signals in parallel.

- Traces must run on top of the ground plane.

- Avoid routing at 90° angles.

- Place bypass capacitors within 2.54mm (0.1 inches) of the device power pin.

- Minimize all trace lengths to reduce series inductance.

- Connect BGND, PGND, and AGND together using a single ground plane.

THESE SPECIFICATIONS DO NOT EXPAND THE TERMS OF FAIRCHILD'S WORLDWIDE TERMS AND CONDITIONS, SPECIFICALLY THE WARRANTY THEREIN, WHICH COVERS THESE PRODUCTS.

LIFE SUPPORT POLICY

FAIRCHILD'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF FAIRCHILD SEMICONDUCTOR CORPORATION.

As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury of the user.

2. A critical component in any component of a life support, device, or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

ANTI-COUNTERFEITING POLICY

Fairchild Semiconductor Corporation's Anti-Counterfeiting Policy. Fairchild's Anti-Counterfeiting Policy is also stated on our external website, www.fairchildsemi.com, under Sales Support.

Counterfeiting of semiconductor parts is a growing problem in the industry. All manufacturers of semiconductor products are experiencing counterfeiting of their parts. Customers who inadvertently purchase counterfeit parts experience many problems such as loss of brand reputation, substandard performance, failed applications, and increased cost of production and manufacturing delays. Fairchild is taking strong measures to protect ourselves and our customers from the proliferation of counterfeit parts. Fairchild strongly encourages customers to purchase Fairchild parts either directly from Fairchild or from Authorized Fairchild Distributors who are listed by country on our web page cited above. Products customers buy either from Fairchild directly or from Authorized Fairchild Distributors are genuine parts, have full traceability, meet Fairchild's quality standards for handling and storage and provide access to Fairchild's full range of up-to-date technical and product information. Fairchild and our Authorized Distributors will stand behind all warranties and will appropriately address any warranty issues that may arise. Fairchild will not provide any warranty coverage or other assistance for parts bought from Unauthorized Sources. Fairchild is committed to combat this global problem and encourage our customers to do their part in stopping this practice by buying direct or from authorized distributors.

PRODUCT STATUS DEFINITIONS

Definition of Terms

Datasheet Identification	Product Status	Definition
Advance Information	Formative / In Design	Datasheet contains the design specifications for product development. Specifications may change in any manner without notice.
Preliminary	First Production	Datasheet contains preliminary data; supplementary data will be published at a later date. Fairchild Semiconductor reserves the right to make changes at any time without notice to improve design.
No Identification Needed	Full Production	Datasheet contains final specifications. Fairchild Semiconductor reserves the right to make changes at any time without notice to improve the design.
Obsolete	Not In Production	Datasheet contains specifications on a product that is discontinued by Fairchild Semiconductor. The datasheet is for reference information only.
