

Automotive-grade, low power, dual, 36 V operational amplifiers

MiniSO8

Product status link

LM2904B

Features

- Up to 36 V operating supply voltage
- Frequency compensation implemented internally
- · Large DC voltage gain: 100 dB
- Wide bandwidth (unity gain): 1.2 MHz (temperature compensated)
- Very low supply current/amplifier, essentially independent of supply voltage
- Low input bias current: 20 nA (temperature compensated)
- Low input offset current: 2 nA
- · Input common-mode voltage range includes negative rail
- Differential input voltage range equal to the power supply voltage
- Large output voltage swing 0 V to Vcc -1.5 V

Applications

- · Telecom equipment
- Power management
- Industrial application
- Automotive

Description

The LM2904B consists of two independent, high gain operational amplifiers (opamps) that have frequency compensation implemented internally. They are designed specifically for automotive and industrial control systems. This circuit operates from a single power supply over a wide range of voltages. The LM2904B is guaranteed up to 36 V supply voltage operation. The low power supply drain is independent of the magnitude of the power supply voltage. Application areas include transducer amplifiers, DC gain blocks and all the conventional op-amp circuits which can now be more easily implemented in single power supply systems. For example, these circuits can be directly supplied from the standard 5 V which is used in logic systems and easily provides the required electronic interfaces without requiring any additional power supply. In linear mode, the input common-mode voltage range includes ground and the output voltage can also swing to ground, even though operated from a single power supply.

2 Absolute maximum ratings and operating conditions

Table 1. Absolute maximum ratings

Symbol	Parameter	Value	Unit
V _{CC}	Supply voltage (1)	±20 or 40	
V _{id}	Differential input voltage ⁽²⁾	±40	V
V _{in}	Input voltage	-0.3 to 40	
	Output short-circuit duration (3)	Infinite	S
l _{in}	Input current: V _{IN} driven negative ⁽⁴⁾	5 mA in DC or 50 mA in AC, (duty cycle = 10 %, T = 1 s)	mA
	Input current: V _{in} driven positive above AMR value ⁽⁵⁾	0.4	
T _{stg}	Storage temperature range	-65 to 150	°C
Tj	Maximum junction temperature	150	
R _{thja}	Thermal resistance junction-to-ambient ⁽⁶⁾ MiniSO8	190	°C/W
R _{thjc}	Thermal resistance junction-to-case ⁽⁶⁾ MiniSO8	39	C/VV
	HBM: human body model ⁽⁷⁾	300	
ESD	MM: machine model (8)	200	V
	CDM: charged device model (9)	1500	

- 1. All voltage values, except differential voltage, are with respect to network ground terminal.
- 2. Differential voltages are the non-inverting input terminal with respect to the inverting input terminal.
- Short-circuits from the output to V_{CC} can cause an excessive heating if (V_{CC} +) > 15 V. The maximum output current
 is approximately 40 mA, independent of the magnitude of V_{CC}. Destructive dissipation can result from simultaneous
 short-circuits on all amplifiers.
- 4. This input current only exists when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistor becoming forward-biased and thereby acting as an input diode clamp. In addition to this diode action, there is an NPN parasitic action on the IC chip. This transistor action can cause the output voltages of the op-amps to go to the V_{CC} voltage level (or to ground for a large overdrive) for the time during which an input is driven negative. This is not destructive and normal output is restored for input voltages above -0.3 V.
- The junction base/substrate of the input PNP transistor polarized in reverse must be protected by a resistor in series with the inputs to limit the input current to 400 μA max. (R = (V_{in} - 32 V)/400 μA).
- 6. Short-circuits can cause an excessive heating and destructive dissipation. Values are typical.
- Human body model: a 100 pF capacitor is charged to the specified voltage, then discharged through a 1.5 kΩ resistor
 between two pins of the device. This is done for all couples of connected pin combinations while the other pins are floating.
- 8. Machine model: a 200 pF capacitor is charged to the specified voltage, then discharged directly between two pins of the device with no external series resistor (internal resistor $< 5 \Omega$). This is done for all couples of connected pin combinations while the other pins are floating.
- 9. Charged device model: all pins and the package are charged together to the specified voltage and then discharged directly to the ground through only one pin. This is done for all pins.

- 1. $V_O = 1.4 \text{ V}$, $5 \text{ V} \le V_{CC} \le 36 \text{ V}$, $0 \le V_{icm} \le V_{CC} 1.5 \text{ V}$.
- 2. The direction of the input current is out of the IC. This current is essentially constant as long as the output is not saturated, so there is no change in the loading charge on the input lines.
- 3. Due to the proximity of external components, ensure that the stray capacitance does not cause coupling between these external parts. This can typically be detected at higher frequencies because this type of capacitance increases.
