XMCP6021/6022/6024

Rail-to-Rail Input/Output, 11 MHz Precision Op Amps

WEB | www.xinboleic.com

RoHS

Descriptions

The XMCP602x family of single-, dual-, and quad- channel operational amplifiers represents a new generation of general-purpose, low-power op-amps. Featuring rail- to-rail input and output (RRIO) swings, low quiescent current (typical 750 μA) combined with a wide bandwidth (11 MHz) and very low noise (8 nV/√Hz at 10 kHz) makes this family very attractive for a variety of battery-powered applications that require a good balance between cost and performance, such as audio outputs, motor phase current sensing, photodiode amplification, barcode scanners and white goods. The low input bias current supports these amplifiers to be used in applications with mega-ohm source impedances.

The robust design of the XMCP602xamplifiers provides ease-of-use to the circuit designer: unity-gain stability with capacitive loads of up to 300 pF, integrated RF/EMI rejection filter, no phase reversal in overdrive conditions, and high electro-static discharge (ESD) protection (4-kV HBM). The XMCP602x amplifiers are optimized for operation at voltages as low as +1.8 V (±0.9 V) and up to +5.5 V (±2.75 V) at the temperature range of 0 ℃ to 70 ℃, and operation at voltages from +2.0 V (±1.0 V) to +5.5 V (±2.75 V) over the extended temperature range of -40℃ to +125 ℃.

The XMCP6021 (single) is available in SOT23-5L package. The XMCP6022 (dual) is offered in SOP-8 and MSOP-8 package. The quad-channel XMCP6024 is offered in SOP-14 and TSSOP-14 package.

Features

- Low Input Offset Voltage: ±0.35 mV Maximum
- Wide Unity-Gain Bandwidth: 11 MHz
- High Slew Rate: 11V/us
- Fast Settling: 0.26us to 0.1%
- Low Noise: 8 nV/√Hz at 10 kHz
- Rail-to-Rail Input and Output
- Internal RF/EMI Filter
- Single 1.8 V to 5.5 V Supply Voltage
- Low Supply Current: 750uA at 5V Supply Per Amplifier
- Extended Temperature Range: I -40°C to +85°C
                               E -40°C to +125°C

SOT23-5

Applications

- Optimized for AEC-Q100 grade 1 applications
- HEV/EV inverter and motor control
- Battery-Powered Instruments
- On-board(OBC) and wireless charger
- ADAS
- Motor Phase Current Sense
- Sensor Signal ConditioningPin Description

Pin Description

Symbol	Description
−IN	Inverting input of the amplifier. The voltage range is from (V_{S-} − 0.1V) to (V_{S+} + 0.1V).
+IN	Non-inverting input of the amplifier. This pin has the same voltage range as −IN.
+V$_S$	Positive power supply.
−V$_S$	Negative power supply.
OUT	Amplifier output.
NC	No internal connection.

Absolute Maximum Ratings（TA=25℃)

In accordance with the Absolute Maximum Rating System (IEC60134).

Parameter	Absolute Maximum Rating
Supply Voltage, V_{S+} to V_{S-}	10.0 V
Signal Input Terminals: Voltage, Current	V_{S-} - 0.5 V to V_{S+} + 0.5 V, ±10 mA
Output Short-Circuit	Continuous
Storage Temperature Range, T_{stg}	-65 ℃ to +150 ℃
Junction Temperature, T_J	150 ℃
Lead Temperature Range (Soldering 10 sec)	260 ℃

Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

Parameter	Tail code	Min.	Max.	Unit
Supply voltage,VS		1.8	5.5	V
Specified temperature	I	−40	85	℃
	E	−40	125	

ESD Rating

Parameter	Item	Value	Unit
Electrostatic Discharge Voltage	Human body model (HBM), per MIL-STD-883J / Method 3015.9 (1)	±5000	V
	Charged device model (CDM), per ESDA/JEDEC JS-002-2014 (2)	±2000	
	Machine model (MM), per JESD22-A115C	±250	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 500-V HBM is possible if necessary precautions are taken.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process. Manufacturing with less than 250-V CDM is possible if necessary precautions are taken

Electrical Characteristics

V_S = 5.0V, T_A = +25°C, V_{CM} = V_S/2, V_O = V_S/2, and R_L = 10kΩ connected to V_S/2, unless otherwise noted.
Boldface limits apply over the specified temperature range, T_A = -40 to +125°C.

Symbol	Parameter	Conditions	Min.	Typ.	Max.	Unit
OFFSET VOLTAGE						
V_{OS}	Input offset voltage	XMCP6021, XMCP6022		±0.10	±0.35	mV
		XMCP6024		±0.12	±0.50

Small Signal Step Response (500 mV).

Application Notes

The XMCP602x is a family of low-power, rail-to-rail input and output operational amplifiers specifically designed for portable applications. These devices operate from 1.8 V to 5.5 V at the temperature range of 0 °C to 70 °C, are unity-gain stable, and suitable for a wide range of general-purpose applications. The class AB output stage is capable of driving ≤ 10- kΩ loads connected to any point between V_{S+} and ground. The input common-mode voltage range includes both rails, and allows the XMCP602x family to be used in virtually any single-supply application .Rail-to-rail input and output swing significantly increases dynamic range, especially in low-supply applications, and makes them ideal for driving sampling analog-to-digital converters (ADCs).

The XMCP602x features 11-MHz bandwidth and 11 -V/μs slew rate with only 750-μA supply current per amplifier ,providing good ac performance at very low power consumption. DC applications are also well served with a low input noise voltage of 8-nV/√Hz at 1-kHz, low input bias current, and an input offset voltage of 0.35-mV maximum. The typical offset voltage drift is 1-μV/°C, over the full temperature range the input offset voltage changes only 100-μV (0.35-mV to 0.45-mV).

OPERATING VOLTAGE

The XMCP602x family is optimized for operation at voltages as low as +1.8 V (±0.9 V) and up to +5.5 V (±2.75 V) at the temperature range of 0 °C to 70 °C, and fully specified and ensured for operation from 2.0 V to 5.5 V (±1.0 V to ±2.75 V). In addition, many specifications apply from −40 °C to +125 °C. Parameters that vary significantly with operating voltages or temperature are illustrated in the Typical Characteristics graphs.

NOTE: Supply voltages (V_{S+} to V_{S-}) higher than +10 V can permanently damage the device.

RAIL-TO-RAIL INPUT

The input common-mode voltage range of the XMCP602x series extends 100-mV beyond the negative and positive supply rails. This performance is achieved with a complementary input stage: an N-channel input differential pair in parallel with a P-channel differential pair. The N-channel pair is active for input voltages close to the positive rail, typically $V_{S+}-$ 1.4 V to the positive supply, whereas the P-channel pair is active for inputs from 100-mV below the negative supply to approximately $V_{S+}-1.4$ V. There is a small transition region, typically $V_{S+}-1.2$ V to $V_{S+}-1$ V, in which both pairs are on. This 200-mV transition region can vary up to 200-mV with process variation. Thus, the transition region (both stages on) can range from $V_{S+}-1.4$ V to $V_{S+}-1.2$ V on the low end, up to $V_{S+}-1$ V to $V_{S+}-0.8$ V on the high end. Within this transition region, PSRR, CMRR, offset voltage, offset drift, and THD can be degraded compared to device operation outside this region.

The typical input bias current of the XMCP602x during normal operation is approximately 1-pA. In overdriven conditions, the bias current can increase significantly. The most common cause of an overdriven condition occurs when the operational amplifier is outside of the linear range of operation. When the output of the operational amplifier is driven to one of the supply rails, the feedback loop requirements cannot be satisfied and a differential input voltage develops across the input pins. This differential input voltage results in activation of parasitic diodes inside the front-end input chopping switches that combine with electromagnetic interference (EMI) filter resistors to create the equivalent circuit. Notice that the input bias current remains within specification in the linear region.

INPUT EMI FILTER AND CLAMP CIRCUIT

Figure 1 shows the input EMI filter and clamp circuit. The XMCP602x op-amps have internal ESD protection diodes (D1 ,D2, D3, and D4) that are connected between the inputs and each supply rail. These diodes protect the input transistors in the event of electrostatic discharge and are reverse biased during normal operation. This protection scheme allows voltages as high as approximately 500-mV beyond the rails to be applied at the input of either terminal without causing permanent damage. These ESD protection current-steering diodes also provide in-circuit, input overdrive protection, as long as the current is limited to 20-mA as stated in the Absolute Maximum Ratings.

Figure 1. Input EMI Filter and Clamp Circuit

Operational amplifiers vary in susceptibility to EMI. If conducted EMI enters the operational amplifier, the dc offset at the amplifier output can shift from its nominal value when EMI is present. This shift is a result of signal rectification associated with the internal semiconductor junctions. Although all operational mplifier pin functions can be affected by EMI, the input pins are likely to be the most susceptible. The EMI filter of the XMCP602x family is composed of two 5-kΩ input series resistors (R_{S1} and R_{S2}), two common-mode capacitors (C_{CM1} and C_{CM2}), and a differential capacitor (C_{DM}). These RC networks set the −3 dB low-pass cutoff frequencies at 35-MHz for common-mode signals, and at 22-MHz for differential signals.

RAIL-TO-RAIL OUTPUT

Designed as a micro-power, low-noise operational amplifier, the XMCP602x delivers a robust output drive capability. A class AB output stage with commonsource transistors is used to achieve full rail-to-rail output swing capability. For resistive loads up to 100- kΩ, the output swings typically to within 5-mV of either supply rail regardless of the power-supply voltage applied. Different load conditions change the ability of the amplifier to swing close to the rails. For resistive loads up to 600-Ω, the output swings typically to within 125-mV of the positive supply rail and within 90-mV of the negative supply rail.

CAPACITIVE LOAD AND STABILITY

The XMCP602x family can safely drive capacitive loads of up to 300-pF in any configuration. As with most amplifiers, driving larger capacitive loads than specified may cause excessive overshoot and ringing, or even oscillation. A heavy capacitive load reduces the phase margin and causes the amplifier frequency response to peak. Peaking corresponds to overshooting or ringing in the time domain. Therefore, it is recommended that external compensation be used if the XMCP602x op-amps must drive a load exceeding 300-pF. This compensation is particularly important in the unity-gain configuration, which is the worst case for stability.

A quick and easy way to stabilize the op-amp for capacitive load drive is by adding a series resistor, RISO, between the amplifier output terminal and the load capacitance, as shown in Figure 2. R_{ISO} isolates the amplifier output and feedback network from the capacitive load. The bigger the RISO resistor value, the more stable V_{OUT} will be. Note that this method results in a loss of gain accuracy because R_{ISO} forms a voltage divider with the R_L.

Figure 2. Indirectly Driving Heavy Capacitive Load

An improvement circuit is shown in Figure 3. It provides DC accuracy as well as AC stability. The RF provides the DC accuracy by connecting the inverting signal with the output. The C_F and R_{ISO} serve to counteract the loss of phase margin by feeding the high frequency component of the output signal back to the amplifier's inverting input, thereby preserving phase margin in the overall feedback loop. For no-buffer configuration, there are two others ways to increase the phase margin: (a) by increasing the amplifier's gain, or (b) by placing a capacitor in parallel with the feedback resistor to counteract the parasitic capacitance associated with inverting node.

Figure 3. Indirectly Driving Heavy Capacitive Load with DC Accuracy

OVERLOAD RECOVERY

Overload recovery is defined as the time required for the operational amplifier output to recover from a saturated state to a linear state. The output devices of the operational amplifier enter a saturation region when the output voltage exceeds the rated operating voltage, either because of the high input voltage or the high gain. After the device enters the saturation region, the charge carriers in the output devices require time to return back to the linear state. After the charge carriers return back to the linear state, the device begins to slew at the specified slew rate. Thus, the propagation delay in case of an overload condition is the sum of the overload recovery time and the slew time. The overload recovery time for the XMCP602x family is approximately 0.3-µs.

EMI REJECTION RATIO

Circuit performance is often adversely affected by high frequency EMI. When the signal strength is low and transmission lines are long, an op-amp must accurately amplify the input signals. However, all op amp pins — the non-inverting input, inverting input, positive supply, negative supply, and output pins — are susceptible to EMI signals. These high frequency signals are coupled into an op-amp by various means, such as conduction, near field radiation, or far field radiation. For example, wires and printed circuit board (PCB) traces can act as antennas and pick up high frequency EMI signals.Amplifiers do not amplify EMI or RF signals due to their relatively low bandwidth. However, due to the nonlinearities of the input devices, op-amps can rectify these out of band signals. When these high frequency signals are rectified, they appear as a dc offset at the output. The XMCP602x op-amps have integrated EMI filters at their input stage. A mathematical method of measuring EMIRR is defined as follows:

$$EMIRR = 20 \log (V_{IN}\_PEAK / \Delta VOS)$$

INPUT-TO-OUTPUT COUPLING

To minimize capacitive coupling, the input and output signal traces should not be parallel. This helps reduce unwanted positive feedback.

MAXIMIZING PERFORMANCE THROUGH PROPER LAYOUT

To achieve the maximum performance of the extremely high input impedance and low offset voltage of the XMCP602x op-amps, care is needed in laying out the circuit board. The PCB surface must remain clean and free of moisture to avoid leakage currents between adjacent traces. Surface coating of the circuit board reduces surface moisture and provides a humidity barrier, reducing parasitic resistance on the board. The use of guard rings around the amplifier inputs further reduces leakage currents. Figure 4 shows proper guard ring configuration and the top view of a surface-mount layout. The guard ring does not need to be a specific width, but it should form a continuous loop around both inputs. By setting the guard ring voltage equal to the voltage at the non-inverting input, parasitic capacitance is minimized as well. For further reduction of leakage currents, components can be mounted to the PCB using Teflon standoff insulators.
Figure 4. Use a guard ring around sensitive pins

Other potential sources of offset error are thermoelectric voltages on the circuit board. This voltage, also called Seebeck voltage, occurs at the junction of two dissimilar metals and is proportional to the temperature of the junction. The most common metallic junctions on a circuit board are solder-to board trace and solder-to-component lead. If the temperature of the PCB at one end of the component is different from the temperature at the other end, the resulting Seebeck voltages are not equal,resulting in a thermal voltage error. This thermocouple error can be reduced by using dummy components to match the thermoelectric error source. Placing the dummy component as close as possible to its partner ensures both Seebeck voltages are equal, thus canceling the thermocouple error. Maintaining a constant ambient temperature on the circuit board further reduces this error. The use of a ground plane helps distribute heat throughout the board and reduces EMI noise pickup

ACTIVE FILTER

The XMCP602x family is well-suited for active filter applications that require a wide bandwidth, fast slew rate ,low-noise, single-supply operational amplifier. Figure 5 shows a 500-kHz, second-order, low-pass filter using the multiple-feedback (MFB) topology. The components have been selected to provide a maximally-flat Butterworth response. Beyond the cut-off frequency, roll-off is –40 dB/dec. The Butterworth response is ideal for applications that require predictable gain characteristics, such as the anti-aliasing filter used in front of an ADC.

Figure 5. Second-Order, Butterworth, 500-kHz Low Pass Filter

One point to observe when considering the MFB filter is that the output is inverted, relative to the input. If this inversion is not required, or not desired, a non-inverting output can be achieved through one of these options:

1. adding an inverting amplifier;
2. adding an additional second-order MFB stage; or
3. using a non-inverting filter topology, such as the Sallen-Key (shown in Figure 6).

Figure 6. Configured as a Three-Pole, 20-kHz, Sallen-Key Filter

MOTOR PHASE CURRENT SENSING

The current sensing amplification shown in Figure 7 has a slew rate of $2\pi f V_{PP}$ for the output of sine wave signal, and has a slew rate of $2f V_{PP}$ for the output of triangular wave signal. In most of motor control systems, the PWM frequency is at 10 kHz to 20 kHz, and one cycle time is 100 µs for a 10 kHz of PWM frequency. In current shunt monitoring for a motor phase, the phase current is converted to a phase voltage signal for ADC sampling. This sampling voltage signal must be settled before entering the ADC. As the Figure 7 shown, the total settling time of a current shunt monitor circuit includes: the rising edge delay time (t_{SR}) due to the op-amp's slew rate, and the measurement settling time (t_{SET}). For a 2- shunt solution of motor phase current sensing, if the minimum duty cycle of the PWM is defined at 5%, and the tSR is required at 20% of a total time window for a phase current monitoring, in case of a 3.3 V motor control system (3.3 V MCU with 12-bit ADC), the op-amp's slew rate should be more than:

$$3.3V \: / \: (100µs \times 5\% \times 20\%) = 3.3 \: V/µs$$

At the same time, the op-amp's bandwidth should be much greater than the PWM frequency, like 10 time at least

t_{SR} – Time delay due to op-amp slew rate
t_{SET} – Measurement settling time
t_{SMP} – Sampling time window

Figure 7. Current Shunt Monitor Circuit

DIFFERENTIAL AMPLIFIER

The circuit shown in Figure 8 performs the difference function. If the resistors ratios are equal $R_4/R_3 = R_2/R_1$, then:

$$V_{OUT} = (V_p - V_n) \times R_2/R_1 + V_{REF}$$

Figure 8. Differential Amplifier

INSTRUMENTATION AMPLIFIER

$$V_{OUT} = (V_1 - V_2)(1 + \frac{R_1}{R_2} + \frac{2R_1}{R_G}) + V_{REF}$$
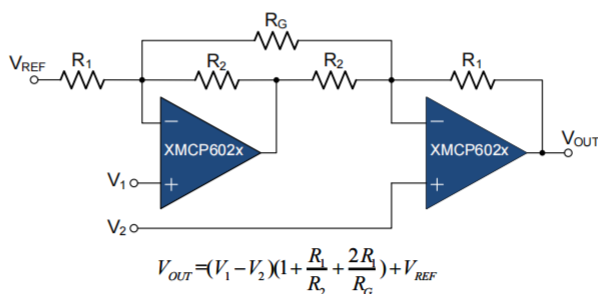

Figure 9. Instrumentation Amplifier

The XMCP602x family is well suited for conditioning sensor signals in battery-powered applications. Figure 9 shows a two op-amp instrumentation amplifier, using the XMCP602x op-amps. The circuit works well for applications requiring rejection of common-mode noise at higher gains. The reference voltage (VREF) is supplied by a low-impedance source. In single voltage supply applications, the VREF is typically $V_S/2$

BUFFERED CHEMICAL SENSORS

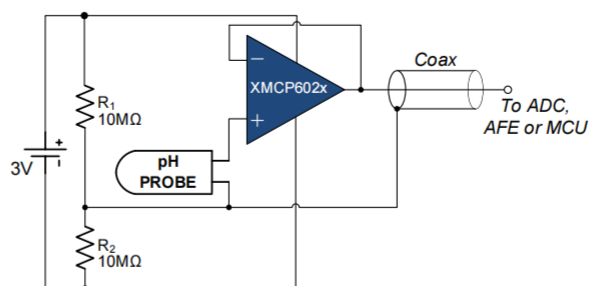

All components contained within the pH probe

Figure 10. Buffered pH Probe

The XMCP602x family has input bias current in the pA range. This is ideal in buffering high impedance chemical sensors, such as pH probes. As an example, the circuit in Figure 10 eliminates expansive low-leakage cables that that is required to connect a pH probe (general purpose combination pH probes, e.g Corning 476540) to metering ICs such as ADC, AFE and/or MCU. A XMCP602x op-amp and a lithium battery are housed in the probe assembly. A conventional low-cost coaxial cable can be used to carry the op-amp's output signal to subsequent ICs for pH reading

Statement：

- XBLW reserves the right to modify the product manual without prior notice! Before placing an order, customers need to confirm whether the obtained information is the latest version and verify the completeness of the relevant information.

- Any semiconductor product may malfunction under specified conditions. When using XBLW products for system design and overall manufacturing, the buyer is responsible for complying with safety standards and taking appropriate safety measures to avoid risks that may cause personal injury or property damage.

- XBLW products have not been licensed for life support, military, and aerospace applications, and therefore XBLW is not responsible for any consequences arising from the use of this product in these areas.

- If any or all XBLW products (including technical data, services) described or contained in this document are subject to any applicable local export control laws and regulations, they may not be exported without an export license from the relevant authorities in accordance with such laws.

- The specifications of any and all XBLW products described or contained in this document specify the performance, characteristics, and functionality of said products in their standalone state, but do not guarantee the performance, characteristics, and functionality of said products installed in Customer's products or equipment. In order to verify symptoms and conditions that cannot be evaluated in a standalone device, the Customer should ultimately evaluate and test the device installed in the Customer's product device.

- XBLW documentation is only allowed to be copied without any alteration of the content and with the relevant authorization. XBLW assumes no responsibility or liability for altered documents.

- XBLW is committed to becoming the preferred semiconductor brand for customers, and XBLW will strive to provide customers with better performance and better quality products.
